Abstract:

Chagas disease and visceral leishmaniasis are two neglected tropical diseases responsible for numerous deaths around the world. For both, current treatments are largely inadequate resulting in a continued need for new drug discovery. As both kinetoplastid parasites do not synthesize purines *de novo*, they rely on purine salvage pathways that allow them to acquire and process purines from the host to meet their demands. Purine nucleoside analogs therefore constitute a logical source of potential antiparasitic agents. Earlier optimization efforts of the natural product tubercidin (7-deazaadenosine) involving modifications to the nucleobase 7-position and the ribofuranose 3'-position led to analogues with potent activity against *Trypanosoma* brucei and *T. cruzi*. The related pyrazolo[3,4-d]pyrimidines (8-aza-7-deazapurines) allopurinol, aminopurinol and the corresponding ribonucleosides already demonstrated *in vitro* anti-*T. cruzi* and antileishmanial activity, but unfortunately were inadequately effective *in vivo*. In this study, we describe the design and synthesis of pyrazolo[3,4-d]pyrimidine nucleosides with 3'- and 7-modifications and assess their potential

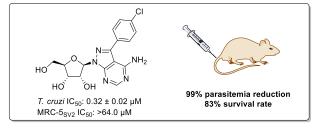

as anti-*T. cruzi* and antileishmanial agents. One compound was selected for *in vivo* evaluation in an acute *T. cruzi* Y-strain mouse model in which oral administration of **44** twice daily at 25 mg/kg for 5 consecutive days led to almost complete (99%) suppression of blood parasitemia and gave 83% of animal survival.

In vivo evaluation in acute Chagas disease mouse model

Introduction

Chagas disease and leishmaniasis are two vector-borne communicable diseases responsible for numerous deaths every year. Characterized by the WHO as neglected tropical diseases (NTD), they occur mainly in populations living in poverty in developing regions around the world, and have a severe impact on the lives of affected persons and their families. ^{1,2} Chagas disease, caused by *Trypanosoma cruzi*, is endemic to Latin and South America where it is still one of the most prevalent public health problems. ³ Migration and specific transmission modes have enabled spreading beyond these geographical boundaries so that it is now considered a global issue. ⁴ Chagas disease starts with an acute symptomatic phase characterized by high-grade parasitemia, which progresses into an asymptomatic chronic state after a few weeks. While most people stay asymptomatic for life, 30-40% will develop severe clinical manifestations after 10-30 years. ^{5,6} Treatment options are limited to nifurtimox and benznidazole, two old drugs that have limited efficacy in the chronic phase of the disease and cause severe side-effects. ⁴ At present, no vaccine is available and effective antiparasitic chemotherapy is therefore key in eliminating this NTD. As the current Chagas disease pipeline is almost empty, there is a pressing need to develop novel, safe and efficacious treatments. ⁷⁻⁹

Leishmaniasis is endemic in 60 countries with Brazil, Ethiopia, India, Kenya, Somalia, South Sudan and Sudan reporting more than 90% of all cases. Depending on the causative *Leishmania* species, the disease exists in two main clinical forms: visceral leishmaniasis (VL) and cutaneous leishmaniasis (CL). The most severe systemic VL form is usually fatal within two years without treatment and is responsible for up to 30 000 deaths every year. Most antileishmanial drugs have been repurposed from other indications. Efficacy varies by geographical region and treatment courses are long, require hospitalization and are associated with significant side effects. While several new chemical entities with distinct mechanisms of action have recently entered clinical trials, there remains a continued need for new drug discovery efforts to fill the early-stage pipeline. New drug candidates should be suitable for field conditions and allow for global use, oral dosing and a short treatment course. 7.20

Unlike their mammalian hosts, both *T. cruzi* and *Leishmania spp*. are obligate auxotrophs for purines, meaning that they lack *de novo* purine biosynthesis and therefore rely on purine salvage to meet purine demand.^{21–23} Consequently, they have developed a complex set of purine salvage enzymes that allows them to acquire and process purines (purine nucleosides and/or nucleobases) from their hosts. Purine (nucleoside) analogs therefore constitute an

interesting pool of potential antiparasitic agents. Indeed, several analogs have been reported that act as inhibitors of purine salvage pathway enzymes or as so-called "subversive substrates" that are selectively activated by enzymes of the invading parasite.^{24–26}

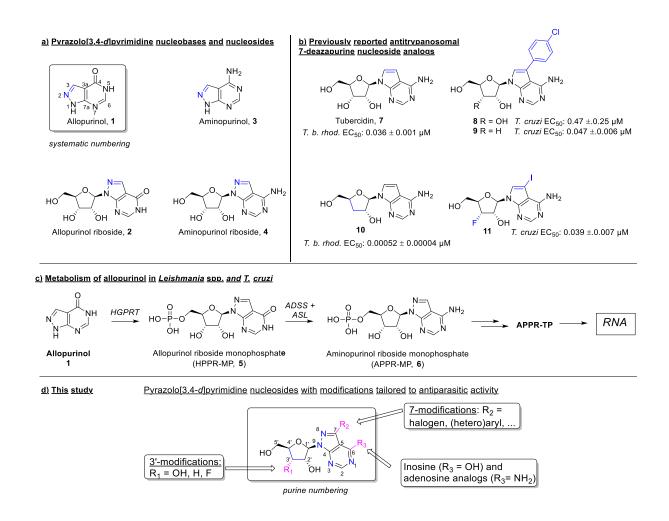

Figure 1. a) Structures of pyrazolo[3,4-*d*]pyrimidines. b) Antitrypanosomal 7-deazapurine nucleosides previously reported by our group. c) Metabolism of allopurinol in *Leishmania* spp. and *T. cruzi*. c) d) Pyrazolo[3,4-*d*]pyrimidine nucleosides reported in this study. Throughout the text, purine numbering is used as shown in Figure 1d while in the experimental part IUPAC numbering is employed.

An example of such a subversive substrate is allopurinol (1) (Figure 1a). Next to its use as a treatment for gout, allopurinol inhibits the growth of several *Leishmania* and *Trypanosoma* species²⁷ in which its mechanism of action has been well investigated.^{28,29} It is selectively metabolized by the parasite to inosine- and adenosine-like nucleotide derivatives 5 and 6, and ultimately to an ATP analog (*i.e.* APPR-TP) that is incorporated in RNA (Figure 1c).^{28–30} Allopurinol has been evaluated in humans for VL treatment with mixed results. Although it

achieved full cures in some patients, it was not satisfactory in monotherapy as first-line treatment due to its static rather than cidal character.³¹ Nevertheless, allopurinol is still used in certain combination regimens for the treatment of CL,11,32,33 and it is the treatment of choice for VL and CL in dogs.³⁴ Allopurinol has also been investigated for the treatment of Chagas disease with mixed outcomes.^{35–37} For example, it proved effective in treating reactivation after heart transplantation.^{38,39} Both in leishmaniasis^{33,40-42} and Chagas disease,⁴³⁻⁴⁵ allopurinol has demonstrated synergism with currently used drugs, demonstrating nucleobase/nucleoside analog could be a valuable addition to the therapeutic arsenal. The in vitro antileishmanial activity of the ribonucleoside of allopurinol (2) is several times higher than allopurinol, but 2 was not further evaluated in vivo due to production difficulties and limited benefit over allopurinol. 46-48 The 6-amino congeners aminopurinol 3 and riboside derivative 4 (Figure 1a) were generally more active in vitro than allopurinol and 2^{46,49,50} which may be due to faster conversion to the same active triphosphate. However, 3 and 4 suffered from cytotoxicity and selectivity concerns. Yet, Avila et al. found aminopurinol to be effective in animal models of both VL and Chagas disease at dosages as much as 300-fold lower than used for allopurinol and well below the toxic dose in humans.^{46,51} Despite these promising data, aminopurinol 3 nor its ribonucleoside 4 were further evaluated for the treatment of leishmaniasis or Chagas disease.

Our group recently reported several 7-deazapurine nucleosides derived from the natural product tubercidin (7) with potent activity against *T. brucei* and *T. cruzi* (Scheme 1c).^{52–56} The introduction of selected substituents on the 7-position (as in 10) led to selective activity against *T. cruzi* and *T. brucei*.⁵² Further removal of the 3'-hydroxyl group afforded compound 8 that was able to elicit full cure in a stage-II *T. brucei* mouse model,⁵⁵ and 9 which displayed high potency against *T. cruzi*.⁵³ A fluorine atom in the 3'-position also proved promising with 11 displaying high anti-*T. cruzi* activity.⁵⁷ Compound 9 was evaluated in a Chagas mouse model, but failed to deliver sterile cure. Furthermore, none of these 7-deazapurine nucleosides displayed selective activity against the phylogenetically related *Leishmania*, which is remarkable given that several nucleoside analogs display antileishmanial potential,^{47,48,58-61} and many nucleosides combine antichagasic and antileishmanial activity.^{46,48,61} Nevertheless, known antileishmanial nucleoside analogs (*e.g.* the pyrazolo[3,4-d]pyrimidines (*vide supra*), carbocyclic inosine,⁶² 9-deazainosine,⁵⁸ Formycin B⁵⁸) contain nucleobase surrogates other than 7-deazapurine, leading us to assume that a 7-deazapurine base is detrimental for antileishmanial activity.

In the search for nucleoside analogs with improved antileismanial activity, we decided to explore nucleosides featuring a pyrazolo[3,4-d]pyrimidine (8-aza-7-deazapurine) nucleobase. Next to 7-deazapurines, pyrazolo[3,4-d]pyrimidines are the only purine isosteres that allow derivatization via 7-modifications, 63,64 such as the ones found beneficial to increase the potency and selectivity of (3'-deoxy)tubercidin. Compared to tubercidin 1,65 aminopurinol riboside 4 is significantly less toxic. Although several 7-modified and 3'-modified pyrazolo[3,4-d]pyrimidine nucleosides have been reported, 66-68 they have not been explored for antiparasitic activity. One exception is 7-bromo-allopurinol riboside, which proved more potent than allopurinol. 69

In this study, we report the synthesis and initial evaluation of a library of 7-substituted and ribofuranose-modified pyrazolo[3,4-d]pyrimidine nucleosides, comprising both inosine-like (allopurinol riboside) and adenosine-like (aminopurinol riboside) analogs. The structure activity-relationships for anti-*T. cruzi* and antileishmanial activity are discussed and one analog was evaluated in an acute Chagas disease mouse model.

Results and discussion

Chemistry

The required brominated and iodinated nucleobase analogs **12** and **13** were readily obtained from 4-amino-1*H*-pyrazolo[3,4-*d*]pyrimidine via reaction with NBS or NIS in DMF at elevated temperature (Scheme 1). While we were also interested in the chloro and fluoro derivatives, chlorination of 4-amino-1*H*-pyrazolo[3,4-*d*]pyrimidine with NCS or fluorination with DAST failed to deliver the desired halogenated heterocycles. **14** was obtained from allopurinol via reaction with bromine in water at 90°C.

<u>Scheme 1.</u> Synthesis of ribofuranose-modified pyrazolo[3,4-*d*]pyrimidine nucleosides. Reagents and conditions: a) NBS, DMF, 60 °C, 91% (for 12), NIS, DMF, 80 °C, 93% (for 13) b) NBS, water, 90°C, 87%; c) 12 (for 18-20), 14 (for 26-28) or 13 (for 34) BF₃.OEt₂, MeNO₂, reflux, 77% (34); d) 0.5M NaOMe in MeOH, 70% over 2 steps (21), 19% over 2 steps (22), 20% over 2 steps (23), 38% over 2 steps (29), 11% over 2 steps (30), 6% over 2 steps (31), 64% (36); e) Pd/C, H₂, 1M aq. NaOAc, MeOH, 61% (4), 82% (24), 66% (25), 54% (2), 83% (32), 80% (33).

7-Bromoallopurinol **14** and 7-bromoaminopurinol **12** were coupled with 1-*O*-acetyl-2,3,5-tri-*O*-benzoyl-β-D-ribofuranose, its 3'-deoxy counterpart **17**⁵³ and 3'-deoxy-3'-fluoro analogue **16.**⁵⁷ Coupling of these three donors with 7-bromoaminopurinol **12** was performed with BF₃.OEt₂ in refluxing nitromethane, as described for **18.**⁶⁹ In all cases, a single product was obtained and no regioisomers were observed. Deprotection with sodium methoxide resulted in **21-23**, and reductive dehalogenation with H₂ and Pd/C in buffered methanol afforded **4-25**. Remarkably, the combined glycosylation-deprotection yields were much lower (~20%) for the 3'-modified analogues compared to that of the ribofuranose **4** (~70%). The correct regiochemistry of the final compounds was confirmed via comparison of the ¹³C NMR spectra of **24** and **25** with that of the literature compound **4**. The chemical shifts of *C*-3 (~133 ppm) and *C*-7a (~154 ppm) (systematic numbering) were identical to reported values, whereas in the *N*-2 regioisomer *C*-3

would be shifted upfield about 10 ppm, and *C*-7a shifted downfield about 5-6 ppm.^{70,71} In the ¹H-¹³C HMBC spectra, *H*-1'-*C*-3 coupling was absent, providing further evidence of the desired *N*-1 regiochemistry.

3-Bromoallopurinol **12** was glycosylated under the same conditions, but for each donor three different products with the same mass were observed on TLC, corresponding to the N-1, N-2 and N-5 regioisomers. The higher-running, less polar spot was the major product and was presumed to be the correct regioisomer⁷² and was isolated. Glycosylation yields were generally lower (\sim 50%) than for the corresponding aminopurinols. The correct regiochemistry of **32** and **33** was verified via comparison of their ¹³C NMR spectra with that of **2**. Compared to the 4-aminonucleosides, the upfield shift of *C*-3 in the *N*-2 isomer is reported to be less pronounced, ⁷² but the values of *C*-3 (\sim 135 ppm) and *C*-7a (\sim 148 ppm) (systematic numbering) were again very similar. Similarly, in this case *H*-1'-*C*-3 coupling was again absent in the ¹H-¹³C HMBC spectra, further confirming *N*-1 attachment of the pyrazolo[3,4-*d*]pyrimidine.

Glycosylation of **15** with 3-iodoaminopurinol afforded **34** in high yield and deprotection in methanolic ammonia furnished **36**. Both **34** and **36** were used for further modifications (*vide infra*). **4** could also be obtained from direct glycosylation of 4-aminopyrazolo[3,4-d]pyrimidine, followed by deprotection.

Scheme 2. Reagents and conditions: a) NBS, DMF, 50°C; b) NaOMe, MeOH, 70°C, 51% over 2 steps; c) **38**, KOH, TDA-1, MeCN, 8%; d) 7N NH₃ in MeOH, 90°C, 76%; e) H₂, Pd(OH)₂/C, NaOAc, MeOH, 46%.

The 2'-deoxy analogs were prepared as described by Seela *et al.* (Scheme 2) ^{64,73–75} **38** was obtained efficiently by bromination of 4-chloro-1*H*-pyrazolo[3,4-d]pyrimidine with NBS, followed by nucleophilic aromatic substitution with sodium methoxide. Anion glycosylation of **38** with commercially available Hoffer's chlorosugar afforded **39** in 8% yield. Simultaneous deprotection and introduction of the 6-amino group to afford **40** was achieved by overnight heating in methanolic ammonia. Reductive dehalogenation via hydrogenation over Pd/C in buffered methanol afforded **41**. Attempted conversion of **39** to the corresponding 6-oxo congener in dilute NaOH solution, as described by Seela for the 3-unsubstituted analog,⁷¹ resulted in glycosidic bond breakage.

Scheme 3. Reagents and conditions: a) boronic acid or trifluoroborate salt, Pd(OAc)₂, TPPTS, Na₂CO₃ (in the case of a boronic acid) or Cs₂CO₃ (when a trifluoroborate salt was used), MeCN/H₂O 1:2, 16-81% (for all compounds except **67** and **65**); b) tributylstannylated heterocycle, Pd(PPh₃)₄, Cul, DMF, 24% (67)*, 66% (65)*; c) H₂, Pd(OH)₂/C, MeOH, 81%.

Further modifications focused on the introduction of substituents on the 7-position of **21**. Different phenyl rings were introduced via aqueous Suzuki coupling reactions with the appropriate arylboronic acids to furnish **42-63** (Scheme 3). Reaction with 4-chloro-3-cyano-

phenylboronic acid gave rise to significant amounts of biphenyl product **75**, which was also isolated. Except for the 2-pyridyl and 2-thiophene substituents in **65** and **67**, which were introduced via Stille coupling, other heterocyclic substituents were also introduced under aqueous Suzuki coupling conditions to furnish **64**, **66** and the substituted 2-thienyl analogues **68-70**. The vinyl- and isopropenyl-compounds **71** and **72** were synthesized via Suzuki reaction with the respective potassium trifluoroborate salts, while *trans-2-vinylphenylboronic* acid was used to obtain **73**. The synthesis of **74** required multiple additions of cyclopropylboronic acid, since reaction with potassium cyclopropyltrifluoroborate proved unsuccesful. Likewise, the 3'-deoxy and 2'-deoxy bromonucleosides **23** and **40** were subjected to Suzuki reaction with 4-chlorophenylboronic acid to afford **76** and **41**. Finally, the isopropenyl group of previously obtained **72** was reduced via catalytic hydrogenation to afford **78**.

Scheme 4. Reagents and conditions: a) phenol (for **79**) or 4-chlorophenol (for **80**), Cul, *N*,*N*-dimethylglycine, Cs₂CO₃, DMA, 120 °C, 5% (**79**), 3% (**80**); b) CuCl, aq. NH₄OH (for **81**) or aq. NHMe (for **82**) or pyrrolidine, 1,4-dioxane/H₂O 1:2 (for **83**), 120 °C, 19% (**81**), 5% (**82**), 16% (83); c) Me₄NCl, Cu₂O, L-proline, 2-methoxyethanol, 120 °C, 7 days; d) 0.5M NaOMe in MeOH, 34% over 2 steps.

Ullman coupling of **21** with phenol or 4-chlorophenol under conditions described for other pyrazolo[3,4-d]pyrimidines⁷⁶ afforded **79** and **80**, respectively (Scheme 4). The yields were very

low (5% and 3%) but provided sufficient amounts of product for preliminary evaluation. The synthesis of **81** via Ullman coupling in aqueous ammonia was already described⁶⁹ and methylamine and pyrrolidine could be coupled under similar conditions to furnish **82** and **83**. In order to introduce a 7-chloro, **18** was subjected to a copper-catalyzed *retro*-Finkelstein reaction.⁷⁷ Although this reaction was sluggish, **79** was obtained in decent yield after deprotection.

The 7-iodo analog **36** served as a useful precursor for another set of analogs (Scheme 5). Sonogashira reaction with phenylacetylene furnished **86**, which was further reduced to **87** via catalytic hydrogenation. Sonogashira reaction with ethynyltrimethylsilane yielded **88**, which was either further reduced to **89** or reacted with azidotrimethylsilane in a copper(I)-catalyzed azide-alkyne cycloaddition to **90**. A nitrile substituent was introduced via a palladium-catalyzed coupling reaction with Zn(CN)₂ to furnish **91**. The nitrile group was further transformed to a tetrazole **92** via a 1,3-dipolar cycloaddition reaction or reduced to the aminomethyl analogue **93** via hydrogenation over Raney Nickel. Alternatively, hydration of the nitrile in basic hydrogen peroxide solution furnished **94**. Attempted hydrolysis of nitrile **91** failed to deliver the carboxylic acid but resulted in cleavage of the *N*-glycosidic bond instead. A trifluoromethyl substituent was introduced via a cross-coupling reaction with *in situ* formed CuCF₃^{56,78} to afford **95**. Deprotection using sodium methoxide then furnished **96**.

Scheme 5. Reagents and conditions: a) phenylacetylene, $PdCl_2(PPh_3)_2$, Cul, DMF/Et₃N 4:1, 40%; b) H_2 , $Pd(OH)_2/C$, MeOH, 89% (87), 74% (89); c) i. ethynyltrimethylsilane, $PdCl_2(PPh_3)_2$, Cul, DMF/Et₃N 4:1, ii. 7N NH₃ in MeOH, 19%; d) TMSN₃, Cul, DMF/MeOH 9:1, 100 °C, 40%; e) $Zn(CN)_2$, $Pd_2(dba)_3$, dppf, DMF, 150 °C, 28%; f) NaN₃, NH₄Cl, LiCl, DMF, 100 °C, 25%; g) H_2 , Raney nickel, MeOH, 10%; h) NH₄OH, H_2O_2 , 25%; i) TMSCF₃, Cul, KF, DMF/NMP 1:1, reflux; j) 0.5M NaOMe in MeOH, 14% over 2 steps.

<u>Scheme 6.</u> Reagents and conditions: a) i. NaH, AcCl, THF, 0 °C to RT, ii. dimethyl sulfate, reflux, iii. H₂NNH₂.H₂O, Et₃N, 38% over 3 steps; b) formamide, 180 °C, 23%; c) thioacetamide, reflux, 36%; d) **98**, BF₃.OEt₂, MeNO₂, reflux; e) 0.5M NaOMe in MeOH, 21% over 2 steps.

To gain access to the methyl-substituted base **98**, 3-methyl-pyrazolo[3,4-*d*]pyrimidine was synthesized *de novo* from malonitrile and acetyl chloride according to the method of Haneman (Scheme 6).⁷⁹ Ring closure of **97** with thioacetamide instead of formamide furnished the bismethylated heterocycle **99**. Glycosylation of **98** afforded **100**, which was deprotected to **101**. Unfortunately, attempted glycosylation of **99** was not successful.

Since a carboxylic acid could not be obtained from the cyano analogue **91**, we looked at other methods to introduce a carbonyl-group on the 7-position. Vilsmeier-Haack formylation of **35** failed and only led to N-formylation of the 6-amino group. Palladium-catalyzed carbonylation reactions with different CO-equivalents were also unsuccessful. 80,81,81,82 Finally, we tried to convert the a vinyl substituent into the correponding aldehyde (Scheme 10). To minimize side reactions, we chose to start from the benzoyl-protected iodide precursor **36**. Suzuki reaction with potassium vinyl trifluoroborate⁸³ afforded **102** in acceptable yields. Oxidative cleavage of the vinyl group **102** was accomplished via Lemieux-Johnson oxidation to afford aldehyde **103**. The carboxylic acid analog **108** could now efficiently be obtained via Pinnick oxidation of **103**. Alternatively, the aldehyde functionality of **103** was further elaborated to a methyl-*N*-morpholino substituent via reductive amination (**104**) or to a difluoromethyl substituent via reaction with DAST (**106**). Deprotection under basic conditions afforded **105** and **107**

respectively. The carboxylic acid functionality was further derivatized to different amides via HCTU-mediated coupling to afford analogs **113-116**. Attempted cyclopropanation of **102** with *in situ* generated difluorocarbene (from BrCF₂CO₂Na⁸⁴) or dichlorocarbene (generated from CHCl₃ and NaOH) failed.

Scheme 6. Reagents and conditions: a) potassium vinyl trifluoroborate, Pd(OAc)₂, PPh₃, Cs₂CO₃, DMF/H₂O 9:1, 100 °C, 38%; b) K₂OsO₄.2H₂O, NalO₄, 2,6-lutidine, 1,4-dioxane/H₂O 3:1, 48%; c) morpholine, NaBH₃CN, AcOH, MeOH/THF 2:1; d) 0.5M NaOMe in MeOH, 64% over 2 steps (**105**), 58% over 2 steps (**107**), 29% over 2 steps (**113**), 28% over 2 steps (**114**), 61% over 2 steps (**115**), 44% over 2 steps (**116**); e) NaClO₂, NaH₂PO₄, H₂O₂, THF/H₂O 6:1, 94%; f) DAST, CH₂Cl₂; g) Aq. NHMe (**109**), pyrrolidine (**110**), aniline (**111**) or benzylamine (**112**), HCTU, DIPEA, DMF.

Biological evaluation

The prepared nucleoside analogs were evaluated *in vitro* for their activity against *T. cruzi* and *L. infantum*. Cytotoxicity was assayed against MRC-5_{SV2} cells (*T. cruzi* host cell) and primary mouse macrophages (PMM, *L. infantum* host cell).

Values in *italics* represent the result of a single determination because of inactivity or overt cytotoxicity. SI: *in vitro* selectivity index is the ratio of the CC₅₀ for the host cell (MRC-5_{SV2} for *T. cruzi*, PMM for *L. inf.*) and the IC₅₀ of the parasite. Benznidazole was included as a reference for *T. cruzi* (IC₅₀ = 2.02 \pm 0.28 μM) and miltefosine as a reference for *L. infantum* (IC₅₀ = 7.47 \pm 2.23 μM).

Although the anti-T. cruzi and antileishmanial activity of allopurinol (1), aminopurinol (3) and their ribonucleosides 2 and 4 are already known, they were included in this study as reference compounds. In accordance with various literature reports 46,51,85 1 and 3 displayed good activity against *T. cruzi* and *L. infantum*. Yet, the 20-fold higher activity and selectivity of aminopurinol (3) compared to allopurinol (1) against *L. infantum* is striking. As mentioned before, 3 has never been evaluated in an in vivo VL model, although it is known to be safe at low doses. 46,51 Introduction of a bromo substituent in position 7 of allopurinol (1) or aminopurinol (3) led to drastic drop in activity, possibly due to impeded conversion by PRTases, which are essential for the activation of nucleobase analogs. The 4-APP ribonucleoside 4 displayed potent activity against both *T. cruzi* and *L. infantum* intracellular amastigotes, as could be expected from literature reports on its activity against *T. cruzi* epimastigotes and *Leishmania* promastigotes. 49,50 In both MRC-5_{SV2} cells and PMM cells, 4 failed to show cytotoxicity up to 64 µM, but similar to 3 it has never been evaluated in vivo. Introduction of a halogen atom on the 7-position (21, 36) of 4 led to a severe decrease in activity against *T. cruzi* and *L. infantum*. This is different from earlier reported results in T. cruzi epimastigotes and Leishmania promastigotes where activity was more comparable to the parent compound 4.49,50 Activity of allopurinol ribonucleoside **2** was comparable to allopurinol.⁸⁵ In our hands, introduction of a bromide on the 7-position (**29**) rendered the compound inactive, which conflicts with a report stating it to be more active than **2** against *L. tropica* intracellular amastigotes.⁶⁹

The combination of aminopurinol (3) and allopurinol (1) with a 3'-deoxy-3'-fluororibofuranose moiety (24 and 32) resulted in inactive compounds. Introduction of a bromide on the 3-position of 24 rendered the compound highly cytotoxic (22). It did not display any selective activity, contrasting with the matched 7-deazapurine nucleoside.⁵⁷ The same was true for the 3'-deoxynucleosides 25-31. While the inactivity of 33 was already noted by Moorman et al.,⁸⁶ the inactivity of 25 was more surprising, as removal of the 3'-hydroxy group resulted in a major increase in activity against *T. brucei* or *T. cruzi* in earlier 7-deazapurine nucleoside series.^{53,55} Again, the introduction of a 7-bromo substituent (23) afforded a cytotoxic compound without any specific antiparasitic activity. The 2'-deoxynucleosides 41 and 40 were also inactive, as was already reported for 41.⁴⁶

Table 2: Evaluation of drug sensitivity of 7-modified nucleoside analogs against *T. cruzi* and *L. infantum.* Cytotoxicity was assayed against human MRC-5_{SV2} cells and primary mouse macrophages (PMM). Values represent mean \pm SEM which originate from 2 to 3 independent experiments and are expressed in μM. Values in parentheses represent the values of the different determinations, as no correct average can be calculated. Values in *italics* represent the result of a single determination because of inactivity or overt cytotoxicity. SI: *in vitro* selectivity index is the ratio of the CC₅₀ for the host cell (MRC-5_{SV2} for *T. cruzi*, PMM for *L. inf.*) and the IC₅₀ of the parasite. Based on the SAR of earlier nucleoside series, 52,53,57,78 which demonstrated that modifications of the 7-position could improve activity, we performed an extensive substituent screen. In a first set of analogs, different substituted phenyl rings were introduced on the 7-position (Table 2). Remarkably, also in this series a 4-chlorophenyl (**44**) proved to confer the best antitrypanosomal activity (IC₅₀ = 0.32 μ M) and was about 50-fold more active than the 7-phenyl analoge **42**. The second most potent para-substituted analog was the 4-methylphenyl substituted compound **45**. Further substitution of the 4-chlorophenyl substituent with a 3-fluoro

(53), methyl (57) or methoxy group (56) failed to potentiate its activity. The 2,4-substituted analogs 62 and 63 were less active than the 3,4-disubstituted analogs. Strikingly, the superiority of this 4-chlorophenyl modification has also been observed for other 7-deazapurine nucleosides and suggests that the chloro substituent is involved in a crucial interaction with with a parasitic target or transporter, rather than just reducing the electron density of the phenyl ring. Removal of the 3'-OH group as in 76 was expected to result in increased anti-*T. cruzi* activity, based on earlier observations with 7-deazapurine nucleosides,⁵³ but surprisingly led to a compound that was 3-fold less active than 44. Nevertheless, 44 is more potent than its 7-deazapurine congener⁵² and displays an improved selectivity profile, with no *in vitro* toxicity in MRC-5_{SV2} or PMM cells in concentrations up to 64 μM. The 2'-deoxy analog 77 displayed reasonably good anti-*T. cruzi* activity but was less potent than both 44 and 76. All phenyl-substituted analogs displayed in Table 2 were inactive against *L. infantum*.

Bioisosteric replacement of the phenyl ring by a thiophene resulted in a loss of activity (67-70) (Table 3). The 5-chlorothiophene and 5-methylthiophene analogs 69 and 68 were 5-10-fold less active than their phenyl counterparts and displayed lower selectivity. Introducing an extra atom or linker between the nucleobase and the phenyl ring was also not tolerated, illustrated by the inactivity of the phenoxy analogs 79 and 80 and the low activity of elongated phenyl analogs 86, 73 and 87. None of these analogs showed any activity against *L. infantum*. A number of nitrogen-containing heterocycles were also introduced on the 7-position (65-92). A 2- or 4-pyridyl substituent (65 and 66), an *N*-methylpyrazole (64) and tetrazole (92) did not lead to any specific activity against *T. cruzi* or *L. infantum*. While 64 and 92 were devoid of MRC-5_{SV2} cytotoxicity, the triazole analog 90 was highly cytotoxic and did also not display any specific antiparasitic activity.

Table 4: Evaluation of drug sensitivity of 7-modified nucleoside analogs against *T. cruzi* and *L. infantum*. Cytotoxicity was assayed against human MRC- 5_{SV2} cells and primary mouse macrophages (PMM). Values represent mean ± SEM which originate from 2 to 3 independent experiments and are expressed in μM. Amongst a series of analogues with small substituents on the 7-position, a nitrile led to reasonable activity against both *T. cruzi* and *L. infantum* (Table 4). The chloro analog **85** was less active against *T. cruzi* but displayed higher selectivity towards MRC-5_{SV2} cells. A trifluoromethyl (**96**) or difluoromethyl (**107**) substituent resulted in cytotoxic compounds that did not display selective antiparasitic activity. Among the carbon-based substituents, the methyl analog **101** and the ethynyl analog **88** displayed moderate anti-*T. cruzi* activity. A vinyl (**71**), ethyl (**89**) or cyclopropyl (**74**) substituent led to inactive compounds, while an isopropenyl (**72**) or isopropyl (**78**) group resulted in cytotoxic compounds with no specific antiparasitic activity. An amine (**81**), methylamine (**82**) or pyrrolidine group (**83**) on the 7-position did not lead to any significant antiparasitic activity, as was the case for an aminomethyl (**93**) or morpholinomethyl (**105**) substituent. The activity of the amide-substituted nucleosides (**94**-**116**) varied: a carboxamide group (**94**) again resulted in a cytotoxic compound, while adding a methyl group on the amide nitrogen (**113**) removed all cytotoxic effects and provided a compound with moderate anti-*T. cruzi* activity. Amide-analogs with bigger groups (**114-116**) were inactive.

Overall, the SAR of the pyrazolo[3,4-d]pyrimidine nucleosides for anti-*T. cruzi* and anti-*L. infantum* activity turned out to be completely different from previously reported 7-deazapurine^{52,53,57} and 1,7-dideazapurine⁷⁸ nucleoside series. As already known from several literature reports, the parent nucleosides aminopurinol riboside **4** and allopurinol riboside **2** displayed good *in vitro* activity against both *T. cruzi* and *L. infantum*. Introduction of a halogen atom on the 7-position had a detrimental effect on the activity against both *T. cruzi* and

L. infantum and modifications at the 3'-position of the ribose moiety, expected to result in more potent compounds based on SAR-studies of earlier nucleoside series, completely abolished activity or resulted in cytotoxic compounds. A substituent screen of the 7-position of 4 revealed highly varying effects on antiparasitic activity and cytotoxicity to MRC-5_{SV2} and PMM. A 4chlorophenyl substituent resulted in a compound with potent anti-T. cruzi activity and devoid of cytotoxic effects in MRC-5_{SV2} or PMM at concentrations up to 64 µM. Contrary to expectations, removal of the 3'-hydroxyl group of 44 resulted in a compound that was 2-3 fold less potent. The insertion of a linker (oxygen, carbon-based, amide) between the oxygen and the phenyl ring was not tolerated. Bioisosteric replacement of the phenyl ring with a thiophene was also not tolerated and resulted in a 10-fold decrease in activity. Other heterocycles in the 7-position resulted in compounds with low antiparasitic activity. The effect of other, smaller substituents varied greatly. Some resulted in moderate anti-T. cruzi activity (e.g. chloride, methyl, ethynyl) while other substituents afforded highly cytotoxic non-selective compounds. Overall, none of the 7-modified analogs displayed good activity against L. infantum suggesting that, regardless of the nature of the heterocyclic nucleobase, substituents on this position are not tolerated. 44 was the most potent analog for T. cruzi and was more active and more selective than its matched 7-deazapurine nucleoside congener.⁵² Because of its potent anti-*T*. cruzi activity and favorable selectivity profile, 44 was selected for further evaluation in an acute Chagas disease mouse model.

Metabolic stability of compound 44

The *in vitro* metabolic stability of **44** was evaluated using male mouse and pooled human liver microsomes (S9 fraction) (Table 5). **44** was not susceptible to Phase-I and Phase-II metabolism in both mouse and human microsomes with 100% of parent drug remaining after 60 minutes. These results favoured further evaluation of **44** in an *in vivo* laboratory rodent model.

Diclofenac (susceptible to Phase-I and Phase-II metabolism) was included as reference to ensure proper assay performance (*data not shown*).

In vivo evaluation of compound 44

To determine its efficacy *in vivo*, **44** was evaluated in an acute Chagas disease model using the Y-strain of *T. cruzi* in Swiss male mice ^{92,93}. **44** was evaluated at 0.25, 2.5 or 25 mg/kg b.i.d or in combination with benznidazole (**44** at 2.5 mg/kg b.i.d + benznidazole at 10 mg/kg q.d.). Compounds were administered orally for 5 consecutive days, starting the administration at parasitemia onset on day 6 post-infection (dpi), which peaked at 8 dpi in untreated animals. **44** at 25 mg/kg gave 99% reduction in parasitemia peak at 8 dpi, which was similar to the optimal q.d. dose of benznidazole at 100 mg/kg. Lower dosages (0.25 and 2.5 mg/kg) only gave partial reduction of parasitemia (43 %). Co-administration of **44** (2.5 mg/kg) and benznidazole (10 mg/kg) reached 71% reduction, which was slightly better than benznidazole alone. However, no mice sustained negative parasitemia hence failing parasitological cure. In the 2.5 mg/mk and 25 mg/kg treatment groups, 5 out of 6 mice (83%) survived until the end of the experiment (34 dpi), similar to benznidazole at 10 mg/kg. In the benznidazole 100 mg/kg group, all mice survived. In the untreated control group, all mice succumbed to the infection by day 27. In the 0.25 mg/kg, only one mouse survived at 34 dpi.

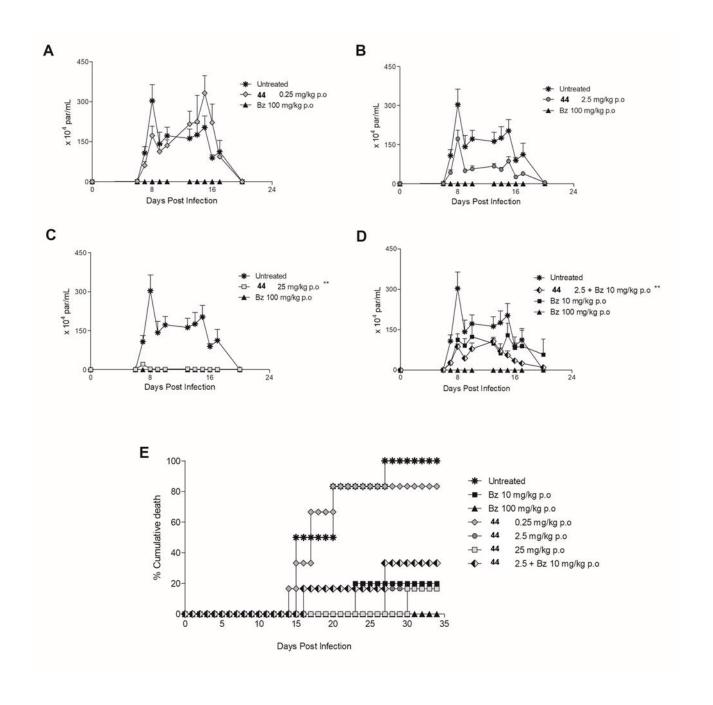

Figure 1. *In vivo* efficacy of **44** administered orally for 5 days in Swiss mice infected with the Y strain of *T. cruzi*. Mortality rates up to 35 dpi (**E**). ** p value ≤0.05.

As the *in vitro T. cruzi* screening was performed with the Tulahuen strain (DTU IV) and *in vivo* assays with the Y strain (DTU II), additional *in vitro* screens were conducted with the latter. The findings confirmed the high potency of **44** against intracellular forms (IC₅₀ = $0.26 \pm 0.03 \mu M$, SI >1900) present in cardiomyocytes (Table 6), similar to the values obtained with the Tulahuen strain intracellular amastigotes. In addition, **44** did not exert cardiotoxicity in 2D and 3D cardiac

cell cultures giving CC₅₀ values up to 500 and 200 µM, respectively. After discarding the potential impact of parasite strain on the in vitro and in vivo outcomes, we next evaluated the activity of 44 (as well as 4) against the non-dividing and highly infective bloodstream trypomastigote form. Both compounds proved to be inactive (IC₅₀ >81 µM), while benznidazole gave an IC₅₀ of 5.7 \pm 0.6 μ M. These results corroborate former studies using pyrrolo[2,3-b]pyridine (1,7-dideazapurine) nucleoside analogues that failed to achieve parasitological cure in treated mice despite parasitemia suppression and high animal survival rates.⁷⁸ The inability to kill bloodstream trypomastigotes may explain the parasitemia recrudescence and thus lack of sterile cure, as has also been reported for other nucleoside analogues.^{53,78} The lack or low activity against bloodstream trypomastigotes resembles that of the azole ergosterol biosynthesis inhibitors that failed in clinical trials for Chagas disease^{87,88} raising the potential relevance of targeting both the intracellular multiplicative amastigotes and the non-replicative trypomastigote forms. Recent findings also highlighted the role of metabolic heterogeneity in drug efficacy upon recalcitrant *T. cruzi* infection.⁸⁹ The authors reported that limiting exogenous glutamine impairs ergosterol biosynthesis inhibitors (azoles) to act upon intracellular amastigotes. In addition to the occurrence of non-replicative forms (like dorment amastigotes and trypomastigotes), the impact of metabolic and environmental heterogeneity must be considered in the search for novel anti-T. cruzi agents as these factors can modulate drug efficacy.

In order to investigate whether host cell permeability could be a limiting factor for the in vivo T. cruzi efficacy or lack of antileishmanial activity of compound 44, we evaluated the effect of 44 against *T. cruzi* in PMM host cells (Table 7). Surprisingly, **44** was completely inactive against T. cruzi in PMM cells, while benznidazole retained its activity in both cell types. In order to rule out drug efflux as the cause of this effect, the experiment was repeated in the presence of the ABC transporter inhibitors verapamil, cyclosporine A and probenecid. In all cases, 44 was inactive, indicating that its inactivity in PMM cells is likely due to permeability issues. These findings might offer further explanation as to why 44 was not able to fully clear T. cruzi infection in vivo. Tissue tropism in Chagas disease has been demonstrated to play an important role in persistence⁹⁰⁻⁹² and limited permeability in certain tissues has also been implicated in the ineffectivity of Posaconazole in cure T. cruzi infections.93 These results could also offer an explanation as to why several of the herein reported nucleoside analogues, as well as others that were previously found to display potent anti-T. cruzi activity, are inactive when evaluated against L. infantum intracellular amastigotes in PMM host cells. 52,94 The origins of this lack of permeability in PMM cells are currently unclear and require further study, a possible explanation could be that an (aryl) substituent on the 7-position of the nucleobase hampers active transport of the nucleoside analogue in the PMM host cells. Furthermore, it would be worthwhile to evaluate if certain nucleoside prodrugs could lead to improved permeability and/or improved in vivo efficacy.

Conclusion

We described the design and synthesis of a library of pyrazolo[3,4-d]pyrimidine nucleosides that were evaluated for *in vitro* activity against *T. cruzi* and *L. infantum* intracellular amastigotes. SAR trends were highly different from earlier reported nucleoside series. Modifications of the

3'-position of the parent adenosine- and inosine-like analogs aminopurinol riboside **4** and allopurinol riboside **2** were detrimental to activity and led to inactive compounds. The introduction of a halogen atom on the 7-position led to a significant decrease in activity. An extensive screen of substitutents on the 7-position **4** revealed varying effects on antiparastic activity and selectivity towards MRC-5_{SV2} and PMM cells. A 4-chlorophenyl substituent on the 7-position (**44**) afforded good anti-*T. cruzi* activity and *selectivity* and was also metabolically stable in human and mouse liver microsomes. **44** was next evaluated in an acute Chagas disease model, resulting in a rapid almost complete reduction in parasitemia. Treatment with **44** led to the survival of 5 out of 6 mice but failed to induce sterile parasitological cure. None of the new analogs showed good *in vitro* activity against *L. infantum*, which could potentially be attributed to limited permeability in the PMM host cell.

Chemistry

General

All reagents and solvents were obtained from standard commercial sources and were of analytical grade. Unless otherwise specified, they were used as received. All moisture sensitive reactions were carried out under argon atmosphere. Reactions were carried out at ambient temperature, unless otherwise indicated. Reactions were monitored via analytical TLC or analytical LC-MS. Analytical TLC was performed on Machery-Nagel® precoated F254 aluminum plates and were visualized by UV followed by staining with basic aq. KMnO₄, Cerium-Molybdate, or sulfuric acid-anisaldehyde spray. Analytical LC-MS was performed on a Waters AutoPurification system (equipped with ACQUITY QDa (mass; 100 - 1000 amu)) and 2998 Photodiode Array (220 – 400 nm)) using a Waters Cortecs® C18 (2.7 µm 100x4.6mm) column and a gradient system of HCOOH in H₂O (0.2 %, v/v)/MeCN at a flow rate of 1.44 mL/min (95:05 to 00:100 in 6.5 minutes or 50:50 to 00:100 in 6.5 minutes). Preparative HPLC was performed on the same system, using a Phenomenex Luna Omega Polar column (250 x 21 mm, 5 μm) and a gradient system of 0.2% formic acid in water/MeCN at a flow rate of 20 mL/min (Gradients are specified in the individual procedures). Column chromatography was performed manually using Machery-Nagel® 60M silica gel (40-63 µm) or on a Reveleris X2 (Grace/Büchi) automated Flash unit employing pre-packed silica columns. Exact mass measurements were performed on a Waters LCT Premier XE™ Time of Flight (ToF) mass

spectrometer equipped with a standard electrospray (ESI) and modular Lockspray™ interface. Samples were infused in a MeCN / water (1:1) + 0.1 % formic acid mixture at 100 µL/min. NMR spectra were recorded on a Varian Mercury 300 MHz spectrometer or a Bruker Avance Neo 400 MHz spectrometer. Chemical shifts (δ) are given in ppm and spectra are referenced to the residual solvent peak. Coupling constants are given in Hz. Melting points were determined on a Büchi-545 apparatus and are uncorrected. Purity was assessed by means of LCMS. All obtained final compounds had purity > 95 %, as assayed by analytical HPLC (UV); unless otherwise indicated.

General procedure A – Large scale BF₃.OEt₂-mediated glycosylation with commercially available 1-*O*-acetyl-2,3,5-tri-*O*-benzoyl-β-D-ribofuranose

The respective pyrazolo[3,4-d]pyrimidine (1.0 eq.) and 1-O-acetyl-tri-O-benzoyl- β -D-ribofuranose (1.5 eq.) were added to dry nitromethane (2.5 mL/mmol). The mixture was heated to reflux, when BF₃.OEt₂ (1.5 eq.) was added, upon which the solids started to dissolve. After 90 minutes of heating at reflux, the solvent was removed *in vacuo*. The resulting oil was dissolved in CH₂Cl₂ (sonicate until fully dissolved) and directly poured on a silica column (preconditioned with CH₂Cl₂). The column was eluted with 100 % CH₂Cl₂ until all excess 1-O-acetyl-tri-O-benzoyl- β -D-ribofuranose had eluted, and then with 5% acetone in CH₂Cl₂ to collect the product.

General procedure B – Small-scale BF₃.OEt₂-mediated glycosylation with protected ribose derivative

The respective pyrazolo[3,4-d]pyrimidine (1.1 eq.) and ribose derivative (1.0 eq.) were added to dry nitromethane (2.5 mL/mmol). The mixture was heated to reflux, when BF₃.OEt₂ (1.0 eq.) was added, upon which the solids started to dissolve. After 90 minutes of heating at, reflux, the solvent was removed *in vacuo*. The resulting oil was dissolved in CH₂Cl₂, celite (1.5 g / g starting material) was added, and the solvent was removed in vacuo. The resulting solid was purified by flash column chromatography to afford the protected nucleoside.

General procedure C – deprotection with NaOMe

Protected nucleoside (1.0 eq.) was dissolved in CH₂Cl₂ (0.5 mL/mmol). MeOH (5 mL/mmol) was added, followed by NaOMe in MeOH (5.4 M, 0.2 mL/mmol). The mixture was stirred at

room temperature or 60 °C (for **36**) until TLC analysis (20 % MeOH in CH₂Cl₂) indicated completion of the reaction. The reaction was neutralized to pH 7 via the addition of 4N HCl, celite (1.5 g / g starting material) was added, and the solvents were removed *in vacuo*. The solid residue was brought onto a silica column and eluted with a mixture of MeOH and CH₂Cl₂ to isolate the final product.

General procedure D – Catalytic hydrogenation in buffered MeOH

The nucleoside analog was dissolved in a mixture of MeOH (8 mL/mmol) and aq. 1M NaOAc (2 mL/mmol). The flask was placed under nitrogen atmosphere and a catalytic amount of Pd/C was added. The atmosphere was exchanged for H₂ and the mixture stirred until TLC analysis (20 % MeOH in CH₂Cl₂) indicated completion of the reaction. The mixture was then filtered over celite, celite was added to the filtrate, and the solvents were removed in *vacuo*. The resulting solid was purified via flash column chromatography to afford the final product.

General procedure E – Suzuki reaction

Compound **21** (1 eq.) or **23** (in the case of **76**, 1 eq.), boronic acid (1.5 eq.) or trifluoroborate salt (1.5 eq.) Na₂CO₃ (when a boronic acid was used, 3 eq.) or Cs₂CO₃ (when a trifluoroborate salt was used, 3 eq.), Pd(OAc)₂ (0.05 eq.) and TPPTS (0.12 eq.) were added to a 10 mL round-bottom flask, equipped with a stir bar. Next, the flask was evacuated and refilled with argon. This procedure was repeated three times in total. Next, MeCN (2 mL / mmol SM) and H₂O (4 mL / mmol SM) were added to the solids under argon. After 5 min of stirring, the mixture was heated to reflux. When the starting material was fully consumed (usually 1 – 3 hours; as monitored by LC-MS analysis), the mixture was cooled to ambient temperature, and neutralized (pH ~ 7) with 4 M aq. HCl. Celite (5 g/ mmol) was added and the mixture was concentrated in vacuo. The residue was purified by flash column chromatography.

General procedure F – Amide coupling

The nucleoside carboxylic acid (1.0 eq.) was dissolved in DMF (10 mL/mmol). DIPEA (3.0 eq.) was added, followed by HCTU (2.5 eq.). After 5 minutes, the respective amine (5.0 eq.) was added and the reaction mixture was stirred overnight. When TLC or LCMS analysis indicated full conversion, the reaction mixture was diluted with excess EtOAc and transferred to a separation funnel. The organic phase was washed with respectively 1N HCl, ag. sat. NaHCO₃

and brine. The organic phase was then dried over Na₂SO₄ and concentrated *in vacuo*. The residue was used directly in the next reaction, without purification.

3-bromo-4-amino-1H-pyrazolo[3,4-d]pyrimidine (12)

4-amino-1*H*-pyrazolo[3,4-*d*]pyrimidine **3** (8.26 g, 61.1 mmol, 1.0 eq.) was dissolved in DMF (60 mL). NBS (11.4 g, 64.2 mmol, 1.05 eq.) was added and the mixture was heated at 60 °C overnight. The mixture was cooled room temperature and poured into ice-cold water (350 mL). The resulting suspension was stirred for 10 minutes at 0 °C and filtered overnight. The solids were collected and dried under high vacuum overnight to afford **12** (11.9 g, 55.7 mmol, 91% yield) as an off-white solid. 1 H NMR (300 MHz, DMSO- d_6) δ 6.91 (1 H, br. s, NH₂'), 7.72 (1 H, br. s, NH₂'') 8.16 (1 H, s, C-6), 13.75 (1 H, br. s, NH) ppm. HRMS (ESI): calculated for C₅H₅BrN₅ ([M+H]⁺): 213.9728, found: 213.9731.

3-iodo-4-amino-1H-pyrazolo[3,4-d]pyrimidine (13)

4-amino-1*H*-pyrazolo[3,4-*d*]pyrimidine **3** (5.68 g, 42.1 mmol, 1.0 eq.) was dissolved in DMF (40 mL). NIS (10.4 g, 46.3 mmol, 1.1 eq.) was added and the mixture was heated at 80 °C overnight. The mixture was cooled room temperature and poured into ice-cold water (350 mL). The resulting suspension was stirred for 10 minutes at 0 °C and filtered overnight. The solids were collected and dried under high vacuum overnight to afford **13** (10.2 g, 39.1 mmol, 93% yield) as a white solid. 1 H NMR (300 MHz, DMSO- d_6) δ 8.16 (1 H, s, C-6), 13.80 (1 H, br. s, NH) ppm. HRMS (ESI): calculated for $C_5H_5IN_5$ ([M+H] $^+$): 261.9590, found: 261.9594.

3-bromo-allopurinol (14)

Allopurinol (4.55 g, 33.4 mmol, 1.0 eq.) was suspended in water (300 mL). Bromine (4.29 mL, 83.6 mmol, 2.5 eq.) was added carefully, and a reflux cooler with a septum was placed on top of the flask. The reflux cooler was connected via vacuum tubing to a large flask containing excess aq. 2M $Na_2S_2O_3$ solution. The reaction mixture was heated at 90 °C overnight and cooled down to room temperature. A mixture of aq. sat. $NaHCO_3$ (75 mL) and aq. 2M $Na_2S_2O_3$ (75 mL) was added through the reflux cooler, after which the reaction mixture turned white. The suspension was cooled down further to 0 °C, stirred for 10 minutes, and filtered. The solids were washed with ice-cold water (3 x), collected, and dried over high vacuum overnight to afford **14** (6.26 g, 29.1 mmol, 87%) as a light-yellow solid. ¹H NMR (300 MHz, DMSO- d_6) δ 8.04

(1 H, d, J=3.8 Hz), 12.22 (1 H, br. s.), 13.98 (1 H, br. s) ppm. ¹³C NMR (75 MHz, DMSO-d₆) δ 104.5 (C-3a), 121.9 (C-3), 149.4 (C-7a), 154.6 (C-6), 157.0 (C-4) ppm. HRMS (ESI): calculated for $C_5H_4BrN_4O$ ([M+H]⁺): 214.9568, found: 214.9572.

3-bromo-4-amino-1-(2',3',5'-tri-O-benzoyl- β -D-ribofuranosyl)pyrazolo[3,4-d]pyrimidine⁶⁹ (18)

Compound **12** (10.3 g, 48.1 mmol, 1.0 eq.) and 1-*O*-acetyl-tri-*O*-benzoyl-β-D-ribofuranose (36.4 g, 72.2 mmol, 1.5 eq.) were subjected to general procedure A to afford **18** (20.3 g, 30.8 mmol, 64% yield) as a brown oil. ¹H NMR (300 MHz, DMSO- d_6) δ 4.51 - 4.67 (2 H, m, H-5', H-5''), 4.82 - 4.89 (1 H, m, H-4'), 6.10 (1 H, t, *J*=5.7 Hz, H-3'), 6.25 (1 H, dd, *J*=5.4, 3.4 Hz, H-2'), 6.67 (1 H, d, *J*=3.2 Hz, H-1'), 7.38 - 7.70 (9 H, m, H_{Phe}), 7.84 - 8.05 (6 H, m, H_{Phe}), 8.24 (1 H, s, H-6) ppm. ¹³C NMR (75 MHz, DMSO- d_6) δ 63.6 (C-5'), 71.3 (C-3'), 74.2 (C-2'), 79.5 (C-4'), 86.4 (C-1'), 100.3 (C-3a), 121.2 (C-3) 128.8 (C_{Phe}), 129.0 (C_{Phe}), 129.2 (C_{Phe}), 129.2 (C_{Phe}), 129.7 (C_{Phe}), 129.8 (C_{Phe}), 129.8 (C_{Phe}), 133.9 (C_{Phe}), 134.3 (C_{Phe}), 134.4(C_{Phe}), 155.5 (C-7a), 157.7 (C-6), 157.8 (C-4), 165.0 (C=O), 165.1 (C=O), 165.9 (C=O) ppm. HRMS (ESI): calculated for C₃₁H₂₅BrN₅O₇ ([M+H]⁺): 658.0937, found: 658.0925.

3-bromo-4-amino-1-(2',5'-di-O-benzoyl-3'-deoxy-3'-fluoro- β -Dribofuranosyl)pyrazolo[3,4-d]pyrimidine (19)

Compound **12** (0.330 g, 1.54 mmol, 1.1 eq.) and compound **16** (0.563 g, 1.40 mmol) were subjected to general procedure B. Purification by flash column chromatography (automated, 0 \rightarrow 5 % MeOH in CH₂Cl₂) afforded semi-pure **19** that was used as such in the next reaction. HRMS (ESI): calculated for C₂₄H₂₀BrFN₅O₅ ([M+H]⁺): 556.0632, found: 556.0590.

3-bromo-4-amino-1-(2',5'-di-O-benzoyl-3'-deoxy- β -D-ribofuranosyl)pyrazolo[3,4-d]pyrimidine (20)

Compound **12** (0.395 g, 1.84 mmol, 1.1 eq.) and compound **17** (0.643 g, 1.67 mmol, 1.0 eq.) were subjected to general procedure B. Purification by flash column chromatography (automated, $0 \rightarrow 5$ % MeOH in CH₂Cl₂) afforded semi-pure **20** that was used as such in the next reaction. HRMS (ESI): calculated for C₂₄H₂₁BrN₅O₅ ([M+H]⁺): 538.726, found: 538.0706.

3-bromo-4-amino-1-β-D-ribofuranosylpyrazolo[3,4-d]pyrimidine (21)

Compound **18** (12.7 g, 19.4 mmol) was subjected to general procedure C (reaction time: 2 hours). Purification via flash column chromatography (manual, first 5% MeOH in CH_2Cl_2 to remove higher-running impurities, and then 15 % MeOH in CH_2Cl_2) to isolate **21** (4.68 g, 13.5 mmol, 70% yield) as a white solid. ¹H NMR (300 MHz, DMSO- d_6) δ 3.38 - 3.47 (1 H, m, H-5'), 3.50 - 3.60 (1 H, m, H-5"), 3.89 (1 H, dd, J=10.0, 4.7 Hz, H-4'), 4.16 (1 H, dd, J=9.4, 4.7 Hz, H-3'), 4.55 (1 H, dd, J=10.8, 5.6 Hz, H-2'), 4.81 (1 H, t, J=5.9 Hz, OH), 5.16 (1 H, d, J=5.3 Hz, OH), 5.40 (1 H, d, J=5.9 Hz, OH), 6.06 (1 H, d, J=5.0 Hz, H-1'), 8.24 (1 H, s, H-6) ppm. ¹³C NMR (75 MHz, DMSO- d_6) δ 62.2 (C-5'), 70.6 (C-3'), 72.9 (C-2'), 85.3 (C-4'), 88.1 (C-1'), 99.7 (C-3a), 119.3 (C-3), 155.0 (C-7a), 157.0 (C-6), 157.4 (C-4) ppm. 3-bromo-4-oxo-1-(2',5'-tri-O-benzoyl-3'-deoxy-3'-fluoro-β-D-ribofuranosyl)pyrazolo[3,4-d]pyrimidine (27)

Compound **14** (0.338 g, 1.57 mmol, 1.1 eq.) and **16** (0.575 g, 1.43 mmol, 1.0 eq.) were subjected to general procedure B. TLC analysis (5 % MeOH in CH_2CI_2) indicated the presence of a major apolar spot, and two smaller more polar spots. The major apolar spot was presumed to be the desired *N*-1 regioisomer⁷² **27** and was isolated via flash chromatography (automated, $0 \rightarrow 5$ % MeOH in CH_2CI_2) and used as such in the next reaction. HRMS (ESI): calculated for $C_{24}H_{19}BrFN_4O_6$ ([M+H]*): 557.0472, found: 557.0457.

3-bromo-4-oxo-1-(2',5'-tri-O-benzoyl-3'-deoxy- β -D-ribofuranosyl)pyrazolo[3,4-d]pyrimidine (28)

Compound **14** (0.348 g, 1.62 mmol, 1.1 eq.) and **17** (0.565 g, 1.47 mmol, 1.0 eq.) were subjected to general procedure B. TLC analysis (5 % MeOH in CH_2CI_2) indicated the presence of a major apolar spot, and two smaller more polar spots. The major apolar spot was presumed to be the desired N-1 regioisomer⁷² **28** and was isolated via flash chromatography (automated, $0 \rightarrow 5$ % MeOH in CH_2CI_2) and used as such in the next reaction. 3-bromo-4-chloropyrazolo[3,4-d]pyrimidine (37)

4-chloropyrazolo[3,4-d]pyrimidine (5.00 g, 32.4 mmol, 1.0 eq.) was dissolved in DMF (50 mL). NBS (6.33 g, 35.6 mmol, 1.1 eq.) was added, and the mixture was heated at 50 °C for 3 hours. H₂O (100 mL) was added, and the mixture was extracted with EtOAc (3 x 150 mL). The combined organic phases were dried over Na₂SO₄ and concentrated in vacuo. The residue was used crude in the next reaction. HRMS (ESI): calculated for C₅H₂BrClN₄ ([M+H]⁺): 232.9230, found: 232.9242.

3-bromo-4-methoxypyrazolo[3,4-d]pyrimidine⁷³ (38)

Compound **37** (crude) was dissolved in MeOH (50 mL). NaOMe (5.4 M in MeOH, 20 mL) was added, and the mixture was heated at 70 °C for 2 hours. The reaction was quenched via the addition of aq. sat. NH₄Cl (200 mL) and H₂O (50 mL). The mixture was extracted with EtOAc (3 x 250 mL) and the combined organic phases were dried over Na₂SO₄ and concentrated in vacuo. The residue was purified by flash column chromatography (manual, petroleum ether/EtOAc 60:40) to afford **38** (3.76 g, 16.4 mmol, 51% yield over 2 steps) as an off-white solid. ¹H NMR (400 MHz, DMSO- d_6) δ 4.10 (3 H, s, CH₃), 8.56 (1 H, s, H-6), 14.27 (1 H, br. s., NH) ppm. ¹³C NMR (101 MHz, DMSO- d_6) δ 54.4 (C-5'), 101.4 (C-3a), 118.1 (C-3), 156.0 C-7a), 156.4 (C-6), 163.0 (C-4) ppm. 4-amino-3-bromo-1-(2'-deoxy-β-D-ribofuranosyl)pyrazolo[3,4-*d*]pyrimidine⁶⁴ (40)

Compound **39** (0.310 g, 0.48 mmol) was stirred in 7N NH₃ in MeOH (20 mL) in a pressure tube at 90 °C for 24 hours. The reaction vessel was cooled down to room temperature before it was opened, and its contents transferred to a pear-shaped flask. The volatiles were removed in vacuo and the residue was adsorbed onto celite and purified by flash column chromatography (automated, $2 \rightarrow 10$ % MeOH in CH₂Cl₂ + 1 % NH₄OH) to afford **40** (120 mg, 0.363 mmol, 76% yield) as a white solid. ¹H NMR (400 MHz, DMSO- d_6) δ 2.25 (1 H, m, J=13.3, 6.8, 4.2 Hz, H-2'), 2.74 (1 H, dt, J=13.0, 6.3 Hz, H-2''), 3.36 (1 H, dt, J=11.6, 5.9 Hz, H-5'), 3.50 (1 H, dt, J=11.4, 5.6 Hz, H-5''), 3.80 (1 H, td, J=5.7, 3.6 Hz, H-4'), 4.34 - 4.46 (1 H, m, H3'), 4.75 (1 H, t, J=5.8 Hz, OH), 5.27 (1 H, d, J=4.6 Hz, OH), 6.51 (1 H, t, J=6.4 Hz, H-1'), 8.23 (1 H, s, H-6) ppm. ¹³C NMR (101 MHz, DMSO- d_6) δ 37.8 (C-2'), 62.3 (C-5'), 70.8 (C-3'), 83.9 (C-4'), 87.7 (C-1'), 99.8 (C-3a), 119.0 (C-3), 154.5 (C-7a), 157.0 (C-6), 157.4 (C-4) ppm. 3-(pyridin-2-yl)-4-amino-1- β -D-ribofuranosylpyrazolo[3,4-d]pyrimidine, formic acid salt (65)

Compound **21** (0.173 g, 0.50 mmol, 1.0 eq.), Pd(PPh₃)₄ (0.087 g, 0.075 mmol, 0.15 eq.) and Cul (0.010 g, 0.05 mmol, 0.1 eq.) were dissolved in dry degassed DMF (2 mL) under Argon. 2-(tributylstannyl)pyridine was added, and the mixture was warmed to 100 °C. After 2 hours, LCMS analysis indicated completion of the reaction. The mixture was cooled to room temperature, diluted with MeOH (15 mL) and MeCN (15 mL) and washed with hexanes (2 x 15 mL). The MeOH/MeCN phase was concentrated in vacuo. The residue was adsorbed onto celite and purified by flash column chromatography (automated, $4 \rightarrow 15\%$ MeOH in CH₂Cl₂), followed by an additional purification by preparative HPLC (0.2% formic acid in H₂O/MeCN 98:02 to 33:67 in 12 minutes) to afford **67** (80 mg, 0.232 mmol, 66% yield) as a white solid. NMR analysis shows the presence of an extra proton, indicating that 65 was isolated as its formic acid salt. ¹H NMR (300 MHz, DMSO- d_6) δ 3.43 - 3.58 (1 H, m, H-5'), 3.60 - 3.74 (1 H, m, H-5"), 3.97 (1 H, dd, J=9.7, 4.7 Hz, H-4"), 4.27 - 4.41 (1 H, m, H-3"), 4.60 - 4.74 (1 H, m, H-2"), 4.88 (1 H, br. s., OH), 5.17 (1 H, br. s., OH), 5.47 (1 H, br. s., OH), 6.21 (1 H, d, *J*=4.4 Hz, H-1'), 7.51 (1 H, ddd, J=7.5, 5.1, 1.2 Hz, H-4_{pvr}), 8.04 (1 H, td, J=7.8, 1.8 Hz, H-5_{pvr}), 8.11 (1 H, d, J=3.2 Hz), 8.24 (1 H, s, H-6), 8.28 (1 H, d, J=7.9 Hz, H-3_{pyr}), 8.74 (1 H, dd, J=4.1, 0.9 Hz, H-6_{pyr}), 9.93 (1 H, d, J=3.8 Hz, NH) ppm. ¹³C NMR (75 MHz, DMSO-d₆) δ 62.4 (C-5'), 71.0 (C-2'), 73.4 (C-3'), 85.4 (C-4'), 88.6 (C-1'), 98.5 (C-3a), 121.0 (C-3_{pvr}), 124.1 (C-5_{pvr}), 138.3 (C-3), 143.7 (C-

A mixture of **21** (150 mg, 0.43 mmol, 1.0 eq.), CuCl (0.006 g, 0.043 mmol, 0.1 eq.) and aqueous methylamine (40%, 30 mL) was heated in a pressure reactor at 130 °C over the weekend. The vessel was cooled to room temperature, and the contents were diluted with MeOH and transferred to a pear-shaped flask. Celite was added, and the mixture was concentrated in vacuo slowly (NHMe evolution!). The solid residue was purified by flash column chromatography ($4 \rightarrow 20\%$ MeOH in CH_2CI_2), followed by an additional purification by preparative RP-HPLC (0.2% formic acid in $H_2O/MeCN$ 98:02 to 33:67 in 12 minutes) to afford **82** (6 mg, 0.020 mmol, 5% yield) as a white solid. ¹H NMR (300 MHz, D_2O) δ 2.85 (3 H, s, CH_3), 3.76 (1 H, dd, J=12.6, 4.1 Hz, H-5'), 3.82 - 3.92 (1 H, m, H-5''), 4.17 (1 H, dd, J=7.0, 3.8 Hz, H-4'), 4.45 (1 H, dd, J=5.0, 3.8 Hz, H-3'), 4.71 - 4.80 (1 H, m, H-2', partially under water peak), 6.07 (1 H, d, J=5.0 Hz, H-1'), 8.04 (1H, s, H-6) ppm. A qualitative ¹³C NMR spectrum could not be obtained from the amount of product available. HRMS (ESI): calculated for $C_{11}H_{17}N_6O_4$ ([M+H]*): 297.1311, found: 297.1318.

3-(1-pyrrolidin-yl)-4-amino-1-β-D-ribofuranosylpyrazolo[3,4-d]pyrimidine (83)

A mixture of **21** (150 mg, 0.43 mmol, 1.0 eq.), CuCl (0.006 g, 0.043 mmol, 0.1 eq.) and pyrrolidine (0.706 mL, 8.60 mmol, 20.0 eq.), 1,4-dioxane (1.5 mL) and H₂O (3 mL) was heated in at 120 °C over the weekend. The mixture was cooled to room temperature and diluted with MeOH. Celite was added, and the mixture was concentrated in vacuo. The solid residue was purified by flash column chromatography (4 \rightarrow 20% MeOH in CH₂Cl₂), followed by an additional purification by preparative RP-HPLC (0.2% formic acid in H₂O/MeCN 98:02 to 33:67 in 12 minutes) to afford **83** (23 mg, 0.068 mmol, 16% yield) as a white solid. ¹H NMR (300 MHz, DMSO- d_6) δ 1.83 - 1.96 (4 H, m, 2 x CH_{2 pyrrolidine}), 3.29 - 3.40 (4 H, m, 2 x CH_{2 pyrrolidine}), 3.45 (1 H, dd, J=11.7, 5.6 Hz, H-5'), 3.59 (1 H, dd, J=11.7, 4.1 Hz, H-5''), 3.87 (1 H, dd, J=9.7, 4.7 Hz, H-4'), 4.21 (1 H, t, J=4.8 Hz, H-3'), 4.50 (1 H, t, J=4.5 Hz, H-2'), 4.81 (1 H, br. s, OH), 5.02 (1 H, br. s, OH), 5.28 (1 H, br. s, OH), 6.02 (1 H, d, J=4.4 Hz, H-1'), 6.98 (2 H, br. s, NH₂), 8.09 (1 H, s, H-6) ppm. ¹³C NMR (75 MHz, DMSO-d₆) δ 24.7 (2 x C_{pyrrolidine}), 50.3 (2 x C_{pyrrolidine}), 62.6 (C-5'), 71.1 (C-2'), 73.1 (C-3'), 84.9 (C-4'), 87.9 (C-1'), 92.1 (C-3a), 150.7 (C-3), 155.4 (C-7a), 155.8

3-chloro-4-amino-1-(2',3',5'-tri-*O*-benzoyl-β-D-ribofuranosyl)pyrazolo[3,4-*d*]pyrimidine (84)

Compound **18** (0.223 g, 0.339 mmol, 1.0 eq.), Cu_2O (0.012 g, 0.085 mmol, 0.25 eq.), Me_4NCl (0.111 g, 1.02 mmol, 3.0 eq.) and L-proline (0.020 g, 0.17 mmol, 0.5 eq.) were suspended in dry degassed 2-methoxy-ethanol (2 mL) under Argon. The mixture was heated at 120 °C for 7 days, when LCMS analysis indicated ~80% conversion and further progression had ceased. The mixture was cooled to room temperature and concentrated *in vacuo*. The residue was used crude in the next reaction. HRMS (ESI): calculated for $C_{31}H_{25}CIN_5O_7$ ([M+H]⁺): 614.1443, found: 614.2593.

3-chloro-4-amino-1-β-D-ribofuranosyl)pyrazolo[3,4-*d*]pyrimidine (85)

The crude **84** from the previous reaction was subjected to general procedure C (reaction time: 1h). Flash column chromatography (automated, $4 \rightarrow 20\%$ MeOH in CH₂Cl₂), followed by an additional purification via preparative RP-HPLC (0.2% formic acid in H₂O/MeCN 98:02 to 88:12 in 4 minutes, then to 77:23 in 5 minutes, then to 33:67 in 3 minutes), afforded **85** (35 mg, 0.116 mmol, 34% yield) as a white solid. ¹H NMR (300 MHz, DMSO- d_6) δ 3.42 (1 H, dt, J=12.0, 5.9 Hz, H-5'), 3.55 (1 H, dt, J=11.7, 5.0 Hz, H-5''), 3.89 (1 H, dd, J=9.7, 4.7 Hz, H-4'), 4.16 (1 H, dd, J=9.7, 4.7 Hz, H-3'), 4.54 (1 H, dd, J=10.5, 5.3 Hz, H-2'), 4.80 (1 H, t, J=5.7 Hz, OH), 5.16 (1 H, d, J=5.3 Hz, OH), 5.40 (1 H, d, J=5.9 Hz, OH), 6.05 (1 H, d, J=4.7 Hz, OH), 7.23 (1 H, br. s, NH), 8.03 (1 H, s, NH), 8.24 (1 H, s, H-6) ppm. ¹³C NMR (75 MHz, DMSO- d_6) δ 62.2 (C-5'), 70.6 (C-2'), 72.9 (C-3'), 85.2 (C-4'), 88.0 (C-1'), 97.5 (C-3a), 132.0 (C-3), 155.1 (C-7a), 157.2 (C-6), 157.3 (C-4) ppm. 3-phenylethynyl-4-amino-1-β-D-ribofuranosylpyrazolo[3,4-*d*]pyrimidine (86)

Compound **36** (0.250 g, 0.636 mmol, 1.0 eq.), $PdCl_2(PPh_3)_2$ (0.022 g, 0.032 mmol, 0.05 eq.) and CuI (0.012 g, 0.1 eq.) were added to a 10 mL round bottom flask. The flask was evacuated and backfilled with argon three times. Then, anhydrous, degassed DMF (2 mL), Et_3N (0.5 mL) and phenylacetylene (0.105 mL, 0.96 mmol, 1.5 eq.) were added. The resulting solution was

stirred at room temperature for 3 hours, when LCMS analysis indicated completion of the reaction. The mixture was concentrated in vacuo, the residue taken up in MeOH, adsorbed onto celite, and purified via flash column chromatography (automated, $2 \rightarrow 12$ % MeOH in CH₂Cl₂) to afford **86** (93 mg, 0.253 mmol, 40% yield) as a white solid. ¹H NMR (300 MHz, DMSO- d_6) δ 3.46 (1 H, dt, J=11.8, 6.0 Hz, H-5'), 3.59 (1 H, dt, J=11.9, 4.9 Hz, H-5''), 3.93 (1 H, dd, J=9.7, 4.7 Hz, H-4'), 4.21 (1 H, dd, J=9.4, 5.0 Hz, H-3'), 4.63 (1 H, dd, J=10.8, 5.0 Hz, H-2'), 4.86 (1 H, t, J=5.9 Hz, OH), 5.18 (1 H, d, J=5.6 Hz, OH), 5.43 (1 H, d, J=6.2 Hz, OH), 6.13 (1 H, d, J=5.0 Hz, H-1'), 7.27 - 7.55 (3 H, m, H_{Phe}), 7.67 - 7.84 (2 H, m, H_{Phe}), 8.28 (1 H, s, H-6) ppm. ¹³C NMR (75 MHz, DMSO- d_6) δ 62.7 (C-5'), 71.2 (C-2'), 73.5 (C-3'), 81.1 (C_{ethynyl}), 85.8 (C-4'), 88.9 (C-1'), 94.1 (C_{ethynyl}), 101.2 (C-3a), 121.5 (C-3), 127.3 (C_{Phe}), 129.1 (C_{Phe}), 130.1 (C_{Phe}), 132.4 (C_{Phe}), 154.7 (C-7a), 157.2 (C-6), 158.2 (C-4) ppm. 3-phenylethyl-4-amino-1-β-D-ribofuranosylpyrazolo[3,4-*d*]pyrimidine (87)

Compound **86** (0.051 g, 0.139 mmol) was dissolved in MeOH (5 mL). The flask was placed under nitrogen atmosphere, and a catalytic amount of Pd(OH)₂/C was added. The atmosphere was exchanged for H₂ and the mixture was stirred for 1 hour, when TLC analysis (20 % MeOH in CH₂Cl₂) indicated completion of the reaction. The mixture was filtered over celite, celite was added to the filtrate, and the solvents were removed under reduced pressure. The solid residue was purified via flash column chromatography (automated, $2 \rightarrow 20\%$ MeOH in CH₂Cl₂) to afford **87** (46 mg, 0.124 mmol, 89% yield) as a white solid.

3-trifluoromethyl-4-amino-1-(2',3',5'-tri-O-benzoyl)- β -D-ribofuranosylpyrazolo[3,4-d|pyrimidine (95)

TMSCF₃ (0.315 mL, 2.13 mmol, 3.0 eq.) was added dropwise over the course of 1 hour to a suspension of CuI (0.406 g, 2.13 mmol, 3.0 eq.) and KF (0.124 g, 2.13 mmol, 3.0 eq.) in a mixture of dry degassed DMF/NMP 1:1 (3 mL). when all solids had dissolved, **34** (0.500 g, 0.709 mmol, 1.0 eq.) in dry degassed DMF/NMP 1:1 (3 mL) was added, and the mixture was heated to reflux. After 3 hours, LC/MS analysis showed full conversion of the starting material, and the reaction was cooled to room temperature. The mixture was diluted with EtOAc (15 mL) and water (5 mL) and the solids were filtered off over Celite®. The filter cake was washed extensively with additional EtOAc (3 x 25 mL), and the combined filtrates were transferred to a separation funnel. Additional water (40 mL) was added, the phases separated, and the organic phase washed twice more with water (25 mL). The organic layer was dried over Na₂SO₄ and concentrated in vacuo. The residue was used as such in the next reaction. HRMS (ESI): calculated for $C_{32}H_{25}F_3N_5O_7$ ([M+H]*): 648.1706, found: 648.1723.

3-trifluoromethyl-4-amino-1-β-D-ribofuranosylpyrazolo[3,4-*a*]pyrimidine (96)

Crude **95** was subjected to general procedure C (reaction time: 1 hour). Purification by flash column chromatography (4 \rightarrow 20 % MeOH in CH₂Cl₂), followed by additional purification by preparative RP-HPLC (0.2% formic acid in H₂O/MeCN 98:02 to 33:67 in 12 minutes) afforded **96** (33 mg, 0.098 mmol, 14% yield over 2 steps) as a white solid. ¹H NMR (300 MHz, DMSO-

5-amino-3-methyl-1H-pyrazole-4-carbonitrile⁹⁸ (97)

A solution of malonitrile (1.11 mL, 20.0 mmol, 1.0 eq.) in THF (20 mL) was cooled to 0 °C. NaH (60% wt. in mineral oil, 1.60 g, 40.0 mmol, 2.0 eq.) was added slowly and the mixture was stirred for 10 minutes. Acetyl chloride (1.43 mL, 20.0 mmol, 1.0 eq.) was added, and the mixture was gradually warmed to room temperature. After 1 hour, dimethyl sulfate (2.28 mL, 24.0 mmol, 1.2 eq.) was added and the mixture heated to reflux. After 3 hours, the mixture was cooled down to room temperature, and Et₃N (6.97 mL, 50.0 mmol, 2.0 eq.) was added, followed by hydrazine hydrate (1.0 mL, 20.0 mmol, 1.0 eq.). The mixture was again heated at reflux temperature for 1 hour and cooled down to room temperature. The mixture was concentrated in vacuo, diluted with H₂O and EtOAc, and transferred to a separation funnel. The phases were separated, and the aqueous phase extracted twice more with EtOAc. The combined organic phases were dried over Na₂SO₄ and concentrated in vacuo. The residue was taken up in MeCN, celite was added, and the solvent was removed under reduced pressure. The solid residue was purified by flash column chromatography (manual, petroleum ether/EtOAc 1:1 and 3:7) to afford **97** (0.930 g, 7.61 mmol, 38% yield) as a yellow sticky foam. ¹H NMR (300 MHz, DMSO d_6) δ 2.12 (3 H, br. s.), 5.72 (2 H, br. s), 11.51 (1 H, br. s) ppm. 4-amino-1-(2',3',5'-tri-*O*-benzoyl-β-D-ribofuranosyl)pyrazolo[3,4-*d*]pyrimidine-3-carboxylic acid (108)

Compound **103** (0.588 g, 0.968 mmol, 1.0 eq) and NaH_2PO_4 (0.035 g, 0.291 mmol, 0.3 eq.) were dissolved in a mixture of THF (9 mL) and H_2O (1.5 mL). Aq. H_2O_2 (30% w/w, 0.110 mL, 0.968 mmol, 1.0 eq.) was added, followed by dropwise addition of a solution of $NaClO_2$ (0.123)

g, 1.36 mmol, 1.4 eq.) in H₂O (1.5 mL). The reaction mixture was stirred overnight, diluted with 0.5 M HCl (20 mL) and extracted with EtOAc (3 x 50 mL). The combined organic phases were dried over Na₂SO₄ and concentrated in vacuo. The residue was taken up in CH₂Cl₂ and adsorbed onto celite. The solid residue was purified by flash column chromatography (0 \rightarrow 10% MeOH in CH₂Cl₂ + 0.1% HOAc) to afford **108** (0.570 g, 0.914 mmol, 94%) as a colourless oil. ¹H NMR (300 MHz, CDCl₃) δ 4.72 (1 H, dd, J=13.2, 6.4 Hz, H-5'), 4.82 - 4.94 (2 H, m, H-5'', H-4'), 6.32 (1 H, t, J=5.6 Hz, H-3'), 6.58 (1 H, dd, J=5.3, 4.1 Hz, H-2'), 6.83 (1 H, d, J=3.8 Hz, H-1'), 7.31 - 7.70 (9 H, m, H_{Bz}), 7.89 - 8.13 (6 H, m, H_{Bz}), 8.18 (1 H, s, H-6), 11.50 (2 H, br. s, NH₂), 12.60 (1 H, br. s, COOH) ppm. ¹³C NMR (75 MHz, CDCl₃) δ 63.8 (C-5'), 71.8 (C-2'), 74.1 (C-3'), 80.7 (C-4'), 89.1 (C-1'), 101.0 (C-3a), 128.4 (C_{Bz}), 128.5 (C_{Bz}), 128.6 (C_{Bz}), 128.8 (C_{Bz}), 129.5 (C_{Bz}), 129.8 (C_{Bz}), 132.0 (C_{Bz}), 132.2 (C_{Bz}), 133.2 (C_{Bz}), 133.6 (C_{Bz}), 133.7 (C_{Bz}), 147.0 (C-3), 152.5 (C-7a), 154.1 (C-6), 155.7 (C-4), 165.0 (COOH), 165.1 (C=O), 166.1 (C=O) ppm. 3-pyrrolidinamido-4-amino-1-(β-D-ribofuranosyl)pyrazolo[3,4-*d*]pyrimidine (114)

Compound **108** (0.080 g, 0.128 mmol) was subjected to General Procedure F, with pyrrolidine as the coupling partner. The obtained residue was subjected to General procedure C (reaction time: 1 hour). Purification via flash column chromatography (automated, 1 \rightarrow 15% MeOH in CH₂Cl₂) afforded **114** (0.006 g, 0.016 mmol, 28% yield over 2 steps) as a white solid. ¹H NMR (300 MHz, CD₃OD) δ 1.90 - 2.12 (4 H, m, 2 x CH_{2 pyrrolidine}), 3.60 - 3.74 (3 H, m, H-5', CH_{2 pyrrolidine}), 3.78 (1 H, dd, J=12.3, 3.2 Hz, H-5''), 4.05 - 4.21 (3 H, m, H-4', CH_{2 pyrrolidine}), 4.50 (1 H, t, J=5.1

Biological evaluation

Compound stock solutions were prepared at 20 mM in 100% DMSO. The compounds were serially pre-diluted (2-fold or 4-fold) in DMSO followed by a further (intermediate) dilution in demineralized water to assure a final in-test DMSO concentration of <1%. Compounds were assayed in 10 concentrations of a 4-fold compound dilution series starting at $64 \mu M$.

Leishmania infantum

L. infantum [MHOM/MA(BE)/67] was used. This strain was maintained in golden hamsters (*Mesocricetus auratus*) obtained from Janvier (Le Genest Saint Isle, France) following approval by the Ethical Committee of the University of Antwerp (ECD2019-10). Amastigotes were collected from the spleens of infected donor hamsters as described elsewhere 100 and spleen parasite burdens were assessed using the Stauber technique. Primary peritoneal mouse macrophages (PMM) were used as host cells and obtained from Swiss mice (Janvier; ethical approval ECD2019-10) after a 2-day peritoneal stimulation with a 2% potato starch suspension. All cultures and assays were conducted at 37°C under an atmosphere of 5% CO₂. Assays were performed in 96well microtiter plates, each well containing 10 µL of the compound dilutions together with 190 μL of macrophage/parasite inoculum (3×10⁴ cells + 4.5×10⁵ parasites/well). The inoculum was prepared in RPMI-1640 medium, supplemented with 200 mM Lglutamine, 16.5 mM NaHCO₃, and 5% inactivated fetal calf serum. The macrophages were infected after 48 hours. The compounds were added after 2 hours of infection. Parasite multiplication was compared to untreated-infected controls (100% growth) and uninfected controls (0% growth). After 5 days incubation, parasite burdens (mean number of amastigotes/macrophage) were microscopically assessed after staining with a 10% Giemsa solution. The results were expressed as % reduction in parasite burden compared to untreated control wells and an IC₅₀ value was calculated.

PMM cytotoxicity

PMM toxicity was assessed during the *in vitro Leishmania* susceptibility assays via microscopic evaluation of cell detachment, lysis, and granulation. Evaluation was done by semi-quantitative scoring (no exact counting was performed) of at least 500 cells distributed over adjacent microscopic fields. The results were expressed as % reduction in normal cells compared to untreated control wells and an CC₅₀ value was determined.

Trypanosoma cruzi

The β -galactosidase expressing *T. cruzi* Tulahuen CL2 strain (nifurtimox-sensitive) was used. This strain was maintained in MRC-5_{SV2} (human lung fibroblast) cells in MEM medium, supplemented with 200 mM L-glutamine,16.5 mM NaHCO₃, and 5% inactivated fetal calf serum. All cultures and assays were conducted at 37°C under an atmosphere of 5% CO₂.

Assays were performed in sterile 96-well microtiter plates, each well containing 10 μ L of the watery compound dilutions together with 190 μ L of MRC-5_{SV2} cell/parasite inoculum (4×10³ cells/well + 4×10⁴ parasites/well). For some assays, PMM were used as *T. cruzi* host cells. For this purpose, 3×10⁴ cells were plated per well and infected two days later with 1.5×10⁴ parasites. To explore the involvement of ABC transporters, compound exposure was also combined with established inhibitors verapamil (8 μ M), probenecid (700 μ M) or cyclosporine A (2 μ M). *T. cruzi* growth was compared to untreated-infected controls (100% growth) and noninfected controls (0% growth) after 7 days incubation at 37°C and 5% CO₂. Parasite burdens were assessed after adding the substrate CPRG (chlorophenolred ß-D-galactopyranoside): 50 μ L/well of a stock solution containing 15.2 mg CPRG + 250 μ L Nonidet in 100 mL PBS. The change in color was measured spectrophotometrically at 540 nm after 4 hours incubation at 37°C. The results were expressed as % reduction in parasite burdens compared to control wells and an IC₅o value was calculated.

*MRC-5*_{SV2} cytotoxicity

MRC- 5_{SV2} cells were cultured in MEM + Earl's salts-medium, supplemented with L-glutamine, NaHCO₃ and 5% inactivated fetal calf serum. All cultures and assays were conducted at 37°C under an atmosphere of 5% CO₂. Assays were performed in sterile 96-well microtiter plates, each well containing 10 µL of the watery compound dilutions together with 190 µL of MRC- 5_{SV2} inoculum (1.5×10⁵ cells/mL). Cell growth was compared to untreated-control wells (100% cell growth) and medium-control wells (0% cell growth). After 3 days incubation, cell viability was assessed fluorimetrically after addition of 50 µL resazurin per well. After 4 hours at 37°C, fluorescence was measured (λ_{ex} 550 nm, λ_{em} 590 nm). The results were expressed as % reduction in cell growth/viability compared to control wells and an IC₅₀ value was determined.

Metabolic stability

Male mouse and pooled human liver microsomes were purchased from a commercial source (Corning) and stored at -80°C. NADPH generating system solutions A and B and UGT reaction mix solutions A and B (Corning) were kept at -20°C. The test compound and the reference compound diclofenac were formulated in DMSO at 10 mM. The microsomal stability assay was carried out based on the BD Biosciences Guidelines for Use (TF000017 Rev1.0) with minor adaptations. The metabolic stability of the compounds was studied through the CYP450 superfamily (Phase-I metabolism) by fortification with reduced nicotinamide adenine dinucleotide phosphate (NADPH) and through uridine glucuronosyl-transferase (UGT) enzymes (Phase-II metabolism) by fortification with uridine diphosphate glucuronic acid (UDPGA). For the CYP450 and other NADPH dependent enzymes, both compounds were incubated at 5 µM together with 0.5 mg/mL liver microsomes in potassium phosphate buffer in a reaction started by the addition of 1 mM NADPH and stopped at the above listed sampling times. At these time points, 20 µl was withdrawn from the reaction mixture and 80 µl cold acetonitrile (ACN), containing the internal standard tolbutamide, was added to inactivate the enzymes and precipitate the protein. The mixture was vortexed for 30 sec and centrifuged at 4°C for 5 min at 15,000 rpm. The supernatant was stored at -80°C until analysis. For the UGT enzymes, both compounds were incubated at 5 μM

together with 0.5 mg/mL liver microsomes in a reaction started by the addition of 2 mM UDPGA cofactor. The corresponding loss of parent compound was determined using liquid chromatography (UPLC) (Waters Aquity[™]) coupled with tandem quadrupole mass spectrometry (MS²) (Waters Xevo[™]), equipped with an electrospray ionization (ESI) interface and operated in multiple reaction monitoring (MRM) mode. The optimal MS parameters and control of the chromatographic separation conditions were tuned in a preceding experiment.

T. cruzi Y-strain bloodstream trypomastigote activity:

Bloodstream trypomastigotes of the Y strain were obtained by cardiac puncture of infected Swiss Webster mice on the parasitaemia peak and drug sensitivity assays performed as described.⁵³

T. cruzi Y-strain intracellular amastigote activity

After 24 h of plating, 2D cardiac cell cultures were infected for 24 h at 37 °C with bloodstream trypomastigotes of *T. cruzi* (Y strain) employing a parasite: host cell ratio of 10:1. Then, the cultures were washed to remove free parasites and treated for 48 h at 37 °C with a serial dilution of the compound in culture medium. After drug exposure, the cultures were rinsed using phosphate buffered saline, fixed and stained with Giemsa as described previously.^{78,101} The mean number of infected host cells and of parasites per infected cells was scored in 200 host cells in two independent experiments each run in duplicate. Only characteristic parasite nuclei and kinetoplasts were considered as surviving parasites since irregular structures could represent parasites undergoing cell death. The compound activity was estimated by calculating the inhibition levels of the inhibition index (II - percentage of infected cells vs the mean number of parasites per infected cell).

Cytotoxicity on cardiac cells

Cardiac 2D and 3D cell cultures were obtained from the heart of Swiss Webster mice embryos, as reported.¹⁰² To prepare the three-dimensional cultures, isolated cardiac

cells were seeded in 96-well U plates (25×10³ cell/well), previously coated with 1% agarose. Both cardiac cultures were sustained in Dulbecco's modified Eagle medium (DMEM; without phenol red; Sigma-Aldrich) supplemented with 5% fetal bovine serum, 2.5 mM CaCl2, 1 mM L-glutamine, streptomycin, and 2% chicken embryo extract, at 37°C. Non-infected cultures were incubated for 48 h at 37°C with crescent concentrations of **44** diluted in supplemented DMEM medium. Morphology was evaluated by light microscopy and cellular viability determined using PrestoBlue®.⁵³ The results are expressed as the difference in reduction between treated and non-treated cultures adopting the manufacturer's instructions. The CC₅₀ (minimum concentration that reduces 50 % of cellular viability) was then determined.¹⁰²

In vivo evaluation

Compounds: Bz (2-nitroimidazole; Laboratório Farmacêutico do Estado de Pernambuco [LAFEPE], Brazil) was used as a reference drug, and was formulated using 3% Tween 80 in distilled water. The nucleoside analogue **44** was diluted using 10% Tween 80 in sterile water.

Mouse infection and treatment

Male Swiss Webster mice (18–20 g; 4–5 weeks of age) were obtained from the animal facilities of ICTB (Institute of Science and Biomodels Technology/Fiocruz/RJ/Brazil). Housing of animals was with a maximum of 6 animals per cage, in a specific-pathogen-free (SPF) room at 20–24 °C under a 12 h light and 12 h dark cycle. All animals were provided sterilized water and chow *ad libitum*. The animals were acclimatized for 7 days before the experiments. At the day of infection (0 dpi), animals were infected by i.p. administration of 10⁴ bloodstream trypomastigotes (Y-strain) originating from an infected donor mouse. Non-infected control mice were age-matched and housed under identical conditions.⁵³ Each experimental group consisted of six animals: untreated (infected vehicle- treated control) and treated (infected and treated with 44 or with benznidazole). Treatment was initiated at the onset of parasitemia (6 dpi) only using mice with a detectable parasitemia. **44** was administered by oral gavage for five

consecutive days at 25, 2.5 and 0.25 mg/kg twice daily. Benznidazole treatment at 10 mg/kg and at the optimal dose (100 mg/kg p.o.) were run in parallel. The efficacy of **44** in co-administration with benznidazole was also evaluated (**44** at 2.5 mg/kg b.i.d + benznidazole at 10 mg/kg/day). All treatments followed a 5-day (6th to 10th dpi) dosing regimen and all compound formulations were freshly prepared before administration. Parasitemia levels in *T. cruzi* assays were individually checked by light microscopic counting of parasites in 5 µL of blood, and mortality rates were checked daily until 34 dpi and expressed as a percentage of cumulative mortality, as described previously ⁹⁵.
